Performance Benchmarks on Ironwood TPU

November 13, 2025

Methodology

- **Theoretical Limit (ms):** This is the minimum possible execution time for a purely compute-bound kernel, often referred to as the "Roofline Latency, computed as Required FLOPS / HW Peak FLOPS/s
  - Required FLOPS FWD: `0.5 (assumed sparsity for causal attn) * batch_size * q_heads * q_seq_len * kv_seq_len * (2 * qk_head_dim + 2 * v_head_dim)`
  - Required FLOPS BWD: `2.5 * Required FLOPS FWD`
  - Ironwood HW Peak FLOPS/s: **1.15 x 10^15**
- **Measured Time (ms):** The actual execution time of the kernel, captured during the benchmark run.
- **MFU (Model FLOPS Utilization):** This metric quantifies how efficiently the kernel utilizes the available compute resources of the TPU. It is expressed as a percentage:

  `MFU (%) = (Theoretical Limit (ms) / Measured Time (ms)) * 100`
- To achieve the best possible performance, various kernel hyperparameters were exhaustively tuned for each configuration of interest. These include parameters that control how data is tiled and processed within the TPU's memory hierarchy, such as block sizes (`block_q`, `block_kv`, etc.) and memory layouts (`q_layout`, `k_layout`, etc.).

Forward Pass (FWD) Benchmarks

Theoretical Limit (ms) / Measured Time (ms) = MFU%
